## 1 Program Design

The structure of the program is shown in the following figure. The function TERM stands for TERMination.

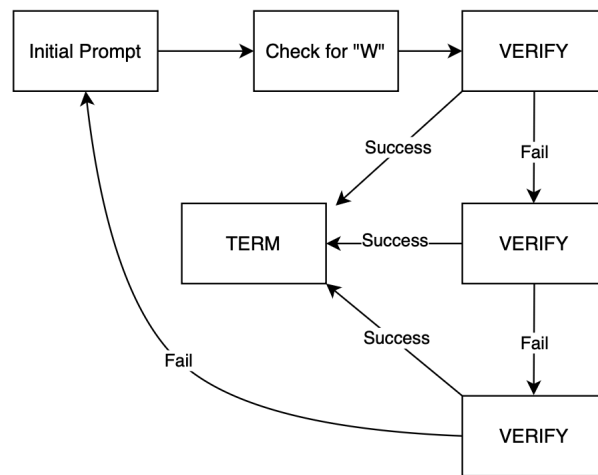

Figure 1: Overall structure

Here is the details of the function VERIFY. It reads a character each time and compare it to the corresponding character in the password. If an unmatching character is found or the length of input exceeds the password. The indicator(i.e. **RO**) is set negative.

Figure 2: Details of VERIFY

## 2 Testing Evidence

Screen recording: [Program test](#)

## 3 Discussion Questions

### 3.1 Functions

Several functions are used in the program. Reasons:

1. Some part of the program may be executed more than once.
2. The use of functions increases readability and makes debugging easier.

### 3.2 Recursion

Recursive functions can be used in the program for checking password. But due to the simplicity of the process (10-character password and 3 attempts), I chose not to use them.

Also, the use of recursion to check password may have a problem when input is super long.

Actually attempts and preparations to use recursion was made.

### 3.3 Preset Prompts

In this program, only 3 attempts are allowed, which means prompts are not too many. In order to keep developing process simple, all prompts are stored using `.STRINGZ` , rather than combine prompts for incorrect inputs, which is a resonable approach if number of attempts allowed may be modified.

---

1	INITPRPT	.STRINGZ	"Welcome to the bank system! Type 'W' to withdraw some fund."
2	SUCCPRPT	.STRINGZ	"Success!"
3	FAILIPRPT	.STRINGZ	"Incorrect password! 2 attempts remaining."
4	FAILIIPRPT	.STRINGZ	"Incorrect password! 1 attempt remaining."

```
5  FAILIIIPRPT .STRINGZ  "Fails."
6  INPUTPRPT   .STRINGZ  "Please input your password:"
7  PSWD        .STRINGZ  "PB22151743"
```

---

### 3.4 Program Security

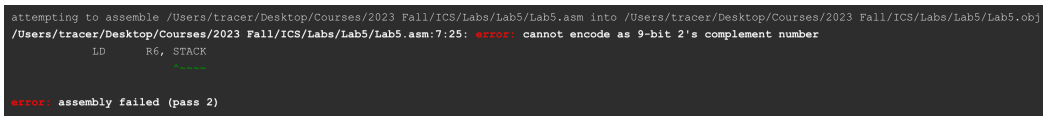

There are two kinds of inputs worth considering: empty input and long input.

In this program, the length of input won't cause a problem. Every time a character is read by the program, it's immediately checked. If the input is longer than the password or a wrong character is found, the indicator will be kept negative.

As for the empty input, A register is set to mark the first character. If the first character is Y, the indicator will be negative.

### 3.5 Challenges

An error occurred when I tried to assemble the program, which I had never met before:

A screenshot of a terminal window showing an assembly error. The text is as follows:

```
attempting to assemble /Users/tracer/Desktop/Courses/2023 Fall/ICS/Labs/Lab5/Lab5.asm into /Users/tracer/Desktop/Courses/2023 Fall/ICS/Labs/Lab5/Lab5.obj
/Users/tracer/Desktop/Courses/2023 Fall/ICS/Labs/Lab5/Lab5.asm:7:25: error: cannot encode as 9-bit 2's complement number
    LD     R6, STACK
    ;      ^~~~~~
error: assembly failed (pass 2)
```

Figure 3: An error

The same instruction worked well in Lab4, which baffled me. Later I realized what the message means: PCoffset was too large.

Solution: move the instruction up.
